# 05. converting between types

**Julia Gallucci HB.Sc, M.Sc, Ph.D.**

Campbell Family Mental Health Research Institute, CAMH

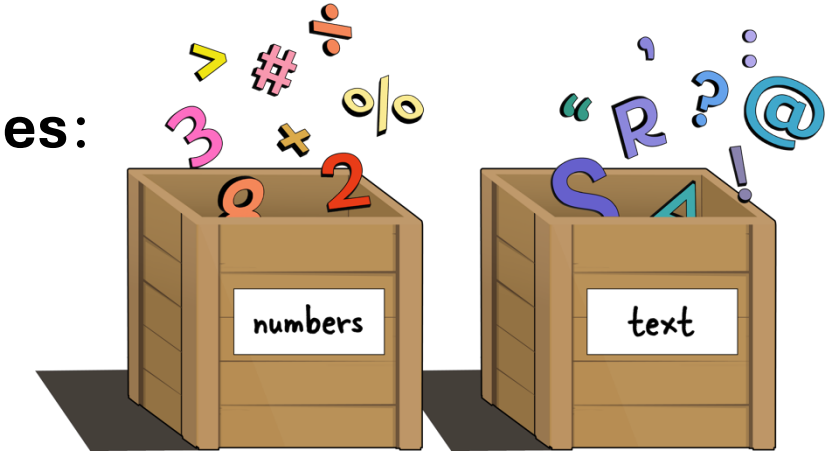
Institute of Medical Science | University of Toronto

# Learning objectives

- Be able to convert data between strings, integers, and floats
- Understand when type conversion may produce errors.

# Converting between types

- Use Python functions to **convert between data types**:
  - `str()` → convert to string
  - `int()` → convert to integer
  - `float()` → convert to float



- Invalid conversions cause errors

```
int('17') # Output: 17
```

```
float('17') # Output: 17.0
```

```
str(37.5) # Output:'37.5'
```

```
'20' + str(37.5) # Output:'2037.5'
```

```
int('me') # ValueError
```

# Exercise

- Try this on your own:
  - Fix the error

```
'The year is' + 2026 # TypeError
```
